Part 1

The Standard Model and its supersymmetric extensions

1.1 The Standard Model of particle physics

The formulation of a relativistic quantum field theory and of spontaneous symmetry breaking (SSB) by the Brout-Englert-Higgs mechanism, allowed to built a theory which is capable to explain almost all observations of particle physics until today [1]. This theory is known as the Standard Model of particle physics (SM). The existence of its last missing piece, the Higgs boson, could be proven at the LHC in the year 2012 [2,3]. 25 The Standard Model is a $SU(3)_C \times SU(2)_L \times SU(1)_Y$ non-abelian gauge theory. "After" 26 spontaneous symmetry breaking, its symmetries are reduced to $SU(3)_C \times U(1)_{EM}$. All 27 particles that were found until today are contained in it¹. Furthermore, it is able to 28 describe three of the four fundamental forces: the strong, weak and electromagnetic force. 29 In the following, a small introduction to the theory and phenomenology of the Standard Model is given. It is not meant as a complete description. The reader is referred to [4–6], 31 for a thorough and extensive introduction.

3 1.1.1 The particle content

It should be first noted, since the Standard Model is a quantum field theory, every field (to be more precise every degree of freedom of a field) can be considered also as a particle and vice versa.

The Standard Model of particle physics contains three different particle types, or three different types of fields. First, there are the so-called "matter particles", which are all spin 1/2 particles in the SM. Second, the forces are described by spin 1 vector bosons.

And finally, in order to give masses to all particles the Standard Model embeds the Higgs boson, a scalar spin 0 particle.

42 Fermions in the Standard Model

The fermionic content can be further subdivided into leptons and quarks. In contrast to quarks, leptons are not strongly interacting, thus they only couple electromagnetically and weakly to other particles. Both, the quarks and the leptons are ordered into three different families. Across these families, all quantum numbers are conserved. They only differ by their mass.

One can argue, that the right-handed neutrino, which is proven to exist, is not contained. But as at least the left-handed neutrino is embedded, we want to ignore that for a moment.

All left-handed particles of each family form a $SU(2)_L$ doublet, which causes the coupling via the weak force. The right-handed partners form SU(2) singlets, thus, don't couple via the weak interaction. As quarks carry one further quantum number, the colour, they are additionally grouped into $SU(3)_C$ triplets.

52 Vector bosons in the Standard Model

As mentioned before, the vector bosons describe three of the four fundamental forces. There is one gauge boson corresponding to every generator of the above mentioned gauge groups. For $U(1)_Y$, it is the *B*-boson, for $SU(2)_L$, there are three gauge bosons $W^{1,2,3}$ and finally eight gauge bosons $G^{1...8}$ for $SU(3)_C$, which are called gluons. As the *B*-field and the neutral W^3_μ -field can mix, "after" SSB the basis can be changed and lead to the well known photon and *Z*-boson.

59 The Higgs boson

65

A somehow extraordinary role plays the Higgs boson, that was predicted already 50 years ago by Peter Higgs [7,8] and could be proven existent by the LHC experiments CMS and ATLAS in 2012 [2,3]. This particle is a consequence of the spontaneous symmetry breaking after rotating three of the four degrees of freedom to masses of the W-and Z-bosons. It is the only known fundamental scalar particle.

An overview of all Standard Model particles and their transformation properties are shown in Table 1.1.1. If particles transform as singlets under $SU(2)_L$ or $SU(3)_C$, they don't couple via the corresponding force. The hypercharges Y are determined by $Q = Y + I_3$, where Q is the electric charge and I_3 is the third component of the weak isospin with $I^a = \sigma^a/2$, σ^a being the Pauli matrices.

1.1.2 The Lagrangian density

In particle physics, the probability of a decay or an interaction between particles can be calculated with the help of the Lagrangian density. The Lagrangian density of the Standard Model is the most general set of Lagrangian terms, that are renormalisable and contain all up to date known particles as well as the above mentioned gauge symmetries.

Table 1.1.1: All particles contained in the Standard Model and their transformation properties under $SU(3)_C \times SU(2)_L \times SU(1)_Y$.

	$SU(3)_C$	$SU(2)_L$	$U(1)_Y$
Fermions:			
$(\nu_L,e_L)^T$	1	2	-1
e_R	1	1	-2
$(u_L, d_L)^T$	3	2	$+\frac{1}{3}$
u_R	3	1	$+\frac{4}{3}$
d_R	3	1	$-\frac{2}{3}$
Vector bosons:			
B_{μ}	1	1	0
W^a_μ	1	3	0
G_{μ}^{a}	8	1	0
Higgs boson: H	1	2	-1

76 It is the following:

$$\mathcal{L} = (D_{\mu}\Phi)^{\dagger} (D^{\mu}\Phi) - \mu^{2}\Phi^{\dagger}\Phi - \frac{\lambda}{4} (\Phi^{\dagger}\Phi)^{2}
+ \bar{L}_{i}^{L}i\not\!D L_{i}^{L} + \bar{e}_{i}^{R}i\not\!D e_{i}^{R} + \bar{Q}_{ib}^{L}i\not\!D Q_{ib}^{L} + \bar{u}_{ib}^{R}i\not\!D u_{ib}^{R} + \bar{d}_{ib}^{R}i\not\!D d_{ib}^{R}
- (Y_{ij}^{e}\bar{L}_{i}^{L}\Phi e_{j}^{R} + Y_{ij}^{u}\bar{Q}_{ib}^{L}\Phi^{c}u_{jb}^{R} + Y_{ij}^{d}\bar{Q}_{ib}^{L}\Phi d_{jb}^{R} + h.c.)
- \frac{1}{4} (B_{\mu\nu}B^{\mu\nu} + W_{\mu\nu}^{a}W^{a\,\mu\nu} + G_{\mu\nu}^{a}G^{a\,\mu\nu}),$$
(1.1.1)

with $D = \gamma_{\mu}D^{\mu}$ and the covariant derivative $D^{\mu} = \partial^{\mu} + ig'Y_WB^{\mu} - igC_1I^aW_a^{\mu} - ig_SC_2T^aG_a^{\mu}$. I^a and I^a denote hereby the generators of the $SU(2)_L$ and $SU(3)_C$, respectively. They are connected to the three Pauli matrices and the eight Gell-Mann matrices by $I^a = \frac{\sigma^a}{2}$ and $I^a = \frac{\sigma^a}{2}$ and the third component of the weak isospin result in the electrical charge $I^a = I^a$ for singlets under $I^a = I^a$ for singlets under $I^a = I^a$ for triplets and $I^a = I^a$ for singlets under $I^a = I^a$ for triplets and $I^a = I^a$ for singlets under $I^a = I^a$ for triplets and $I^a = I^a$ for the Higgs field and its potential. Via this Higgs field, it is possible to give masses to the I^a -and I^a -bosons as well as the fermions. This will be explained in detail in the following Section 1.1.3. The second line describes the kinetic terms of the leptons and quarks. The index i represents the three different families (i = 1, 2, 3). Since they are spin 1/2 particles, they can be described with the help of Dirac spinors. The left-handed leptons and quarks are described as $SU(2)_L$ doublets, $L_I^L = (\nu_{eL}, e_L)_i$, $Q_I^L = (u_L, d_L)_i$, the right-handed as singlets under $SU(2)_L e_i^R$, u_i^R , d_i^R . Quarks carry a further quantum number, the colour, which is indicated by the index b with b = 1, 2, 3. Quarks transform as triplets under the $SU(3)_C$ gauge group. The third line contains the interaction terms between the fermions and the Higgs boson, called Yukawa interactions. These terms lead after SSB to the fermion mass terms, as can be seen later. The last line correspond to the kinetic terms of the gauge fields. These are connected to the field strength tensors by

$$B^{\mu\nu} \equiv \partial^{\mu}B^{\nu} - \partial^{\nu}B^{\mu}$$

$$W^{\mu\nu} \equiv \partial^{\mu}W^{\nu} - \partial^{\nu}W^{\mu} - ig\left[W^{\mu}, W^{\nu}\right]$$

$$= \left(\partial^{\mu}W_{i}^{\nu} - \partial^{\nu}W_{i}^{\mu} + g\epsilon_{ijk}W_{j}^{\mu}W_{k}^{\nu}\right)\frac{\sigma_{i}}{2} \equiv \frac{\sigma_{i}}{2}W_{a}^{\mu\nu}$$

$$G^{\mu\nu} \equiv \partial^{\mu}G^{\nu} - \partial^{\nu}G^{\mu} - ig_{S}\left[G^{\mu}, G^{\nu}\right]$$

$$= \left(\partial^{\mu}G_{a}^{\nu} - \partial^{\nu}G_{a}^{\mu} + g_{S}f_{abc}G_{b}^{\mu}G_{b}^{\nu}\right)\frac{\lambda_{a}}{2} \equiv \frac{\lambda_{a}}{2}G_{a}^{\mu\nu}.$$

$$(1.1.2)$$

- The factors ϵ_{ijk} and f_{abc} are hereby the structure constants of the corresponding lie groups.
- The summation over all indices that appear twice is included.

1.1.3 The Brout-Englert-Higgs mechanism

An essential ingredient of the Standard Model is the Brout-Englert-Higgs mechanism (BEH 99 mechanism), earlier also called Higgs mechanism. It was developed by Peter Higgs, Robert 100 Brout and François Englert in 1960s [7–12]. Based on a work from Sheldon Glashow [13], 101 Steven Weinberg and Abdus Salam later applied it on a $SU(2) \times U(1)$ gauge theory [14,15]. 102 By this, a renormalisable theory of the weak and the electromagnetic theory was born. 103 Together with the theory of strong interaction, the formulation of the Standard Model 104 was thus by this time complete. 105

Mass terms of the gauge bosons

106

Due to the BEH mechanism, it is possible to give masses to the W^{\pm} -and Z-bosons. A 107 scalar field Φ (Higgs field) is required, which has a non-zero vacuum expectation value. 108 This is possible, when the mass parameter μ in front of the bilinear term in line one of 109 Eq. (1.1.1) is smaller than zero and $\lambda > 0$ at the same time. 110 111

The resulting potential of the Higgs field is then the famous "Mexican hat" potential.

Expanding the Lagrangian density around the minimum of $\Phi = (0, v)$, the gauge symmetries of $SU(2)_L \times U(1)_Y$ are spontaneously broken and only a remaining electrical charge conserving symmetry $U(1)_{EM}$ remains. After an unitary transformation, three of the four degrees of freedom of the Higgs field are absorbed by the gauge fields. Thus, "after" SSB, the part of the Lagrangian containing the scalar field is as follows

$$\mathcal{L}_{\text{Higgs}} = \frac{1}{2} \left(\partial_{\mu} h^{0} \right)^{\dagger} \left(\partial^{\mu} h^{0} \right) - \mu^{2} \left(h^{0} \right)^{2} + \frac{1}{2} v^{2} g^{2} W_{\mu}^{-} W^{+ \mu} + \frac{1}{4} v^{2} \left(g^{2} + g'^{2} \right) Z_{\mu} Z^{\mu}$$
+ interaction terms (1.1.3)

One kinetic and one mass term for one of the degrees of freedom of the Higgs fields remains, which is the Higgs boson (h^0). Furthermore, three of the four gauge bosons require a mass. The remaining gauge boson, being the photon remains massless because of the conserved $U(1)_{EM}$ gauge symmetry.

The mass eigenstates of the gauge bosons in Eq. (1.1.3) are obviously different to the interaction eigenstates in Eq. (1.1.1). The diagonalisation of the neutral mass matrices is described by the Weinberg angle θ_W

$$\begin{pmatrix} A_{\mu} \\ Z_{\mu} \end{pmatrix} = \begin{pmatrix} \cos \theta_W & -\sin \theta_W \\ \sin \theta_W & \cos \theta_W \end{pmatrix} \begin{pmatrix} B_{\mu} \\ W_{\mu}^3 \end{pmatrix}.$$
(1.1.4)

For the charged gauge bosons, the relation between $W_{1,2}$ and W^{\pm} is the following

$$W_{\mu}^{\pm} = \frac{1}{\sqrt{2}} \left[W_{\mu}^{1} \mp W_{\mu}^{2} \right]. \tag{1.1.5}$$

Consequently, the masses of the gauge boson are the following

$$M_H = \sqrt{2}\mu$$

$$M_W = \frac{g}{\sqrt{2}} v$$

$$M_Z = \frac{1}{\sqrt{2}} v \sqrt{g^2 + g'^2}$$

$$M_{\gamma} = 0.$$
(1.1.6)

The first direct observation of the Z-and W^{\pm} -bosons was made in $p\bar{p}$ -collisions in the year 1983 at the Super Proton Synchrotron (SPS) at CERN [16, 17]. The experimental values of the masses are $m_Z=91.1876\pm0.0021\,\mathrm{GeV}$ and $m_{W^{\pm}}=80.385\pm0.015\,\mathrm{GeV}$ [18]. Finally, as mentioned several times before, the Higgs boson was found at the LHC in the year 2012 [2,3]. The mass is measured to $m_{h^0}=125.09\pm0.21(\mathrm{stat.})\pm0.11(\mathrm{sys.})\,\mathrm{GeV}$ [19].

148

149

150

151

152

131 Mass terms of the fermions

Fermion mass terms cannot be easily inserted into the Lagrangian density in Eq. (1.1.1), since they would violate the imposed gauge symmetries. With the help of the BEH mechanism it is possible to generate fermion mass terms via the Yukawa interactions terms (line three of Eq. (1.1.1)). After spontaneous symmetry breaking, the Yukawa interactions lead to the following mass terms (colour indices are suppressed)

$$\mathcal{L}_{\text{Yukawa}} = -\left(Y_{ij}^{e} \, v \, \bar{e}_{i}^{L} e_{j}^{R} + Y_{ij}^{u} \, v \, \bar{u}_{i}^{L} u_{j}^{R} + Y_{ij}^{d} \, v \, \bar{d}_{i}^{L} d_{j}^{R} + h.c.\right)$$
+ interaction terms
$$(1.1.7)$$

The fermion masses are thus described by the following mass matrices

$$M_{ij}^e = Y_{ij}^e v$$
 $M_{ij}^u = Y_{ij}^u v$ $M_{ij}^d = Y_{ij}^d v$ (1.1.8)

Since the Standard Model does not contain right-handed neutrinos, there are no gauge invariant Yukawa interactions, that could produce mass terms for neutrinos.

1.1.4 Limitations of the Standard Model

Despite the great success of the Standard Model, there remain observations and theoretical considerations that cannot be answered within the SM. In the following, the most important of such "limitations" shall be reviewed.

First of all, the Standard Model suffers of the so-called hierarchy problem. By this, the problem is addressed that quadratic divergencies occur in the calculation of the Higgs self-coupling. The appearance of infinities is not uncommon in higher order calculations and happens for all particles. Still, for scalar particles the infinite term is quadratically divergent, which makes a huge difference compared to the logarithmic divergencies for fermion self-energies. When considering the Standard Model valid up to the Planck scale, an extraordinary fine-tuning would be needed to cancel a large bare mass with large counter terms

$$m_{h^0}^{{\rm ren}\,2} = m_{h^0}^{{\rm bare}\,2} + \Delta m_{h^0}^2. \eqno(1.1.9)$$

to end up with a mass of about 125 GeV. Thus, this renormalisation procedure, even if mathematically possible, is regarded as highly unnatural in physics. The question which is usually imposed is, why is the Higgs mass so small, when there are such massive corrections to the bare bass? A formulation of naturalness was given by t'Hooft in 1977 [20]. He stated, that a small parameter can be regarded only natural, if the symmetries of the theory are enhanced by setting this parameter to zero. In the Standard Model, though, there is no enhancement of the symmetries of the Lagrangian by setting $\mu = 0$, thus the small mass of the Higgs boson compared to the Planck scale is considered as highly unnatural.

A further and probably the most striking shortcoming of the Standard Model is the missing fourth fundamental force, the gravitational force. Within the SM, it is not possible to add renormalisable terms, that can describe the gravitational force. Although, gravity is not important for particle physics at energies that are accessible at current particle colliders (it only becomes important at the Planck scale $\sim 10^{19}\,\mathrm{GeV}$), the fact that it cannot be embedded into the Standard Model leads to an understanding of the SM as effective theory, only valid for lower energies. Thus, it is obviously not an ultimate theory and something must be beyond.

Furthermore, in particle physics there is always the wish to describe nature with a theory as simple as possible. This usually implies the effort to embed the Standard Model into a higher symmetry group. To achieve a simplification by unifying the three fundamental forces is usually done within so-called Grand-Unified-Theories (GUTs). Calculating the running of the coupling constants in the Standard Model, the couplings seem to meet at a scale of $M_{\rm GUT} \sim 10^{15} \, {\rm GeV}$. Unfortunately, they don't meet exactly. Therefore, a unification is not achievable in the Standard Model under the assumption that there are no new particles up to the GUT scale.

Finally, there is experimental evidence, which cannot be explained within the Standard Model. Astrophysical observations suggest that there is a large amount of dark matter (DM) in the universe, that cannot be explained with the particle content of the Standard Model. Measurements of the velocity curves of galaxies, e. g. M33 [21] show discrepancies between the observed velocities and the predicted velocities by the visible matter. The share of non-visible matter to the total amount of matter in the universe is estimated to be 84% [22]. Unfortunately, there is no suitable (only weakly interacting) candidate within the SM, that can make up the full DM contribution.

In the following Chapter 1.2, a theory is introduced, that can address most of the above mentioned problems. This theory is called Supersymmetry.

1.2 Supersymmetry

As noted in the last chapter, the Higgs boson mass suffers from quadratic divergencies through radiative corrections. The reason for the quadratic divergencies is due to the

fact, that the Lagrangian density does not contain further symmetries for $\mu \to 0$. This behaviour is typical for scalar particles. For fermions, on the other hand, there is a further symmetry for $m_f=0$. The Lagrangian density becomes invariant under chiral transformations of the form $\Psi \to e^{i\vec{\alpha}\frac{\vec{\sigma}}{2}\gamma_5}\Psi$. Although the mass terms of the fermions break this symmetry, it protects the fermions against large radiative corrections.

Due to these considerations, it seems natural to protect also the scalar mass by an additional symmetry. A work from Golfand and Likhtman in the year 1971 stated that an extension of the Poincaré algebra is possible via fermionic generators [23]. R. Haag, J. Lopuszanski and M. Sohnius finalised these considerations by showing that with the help of fermionic generators a connection between space-time symmetries and internal symmetries is possible [24]. The extensions of a symmetry group by fermionic generators is called Supersymmetry (SUSY). These were the foundation of supersymmetric theories.

205

In the following, few aspects of supersymmetric theories are discussed. For a detailed introduction the reader is referred to [25–27].

In the subsequent sections, the descriptions is restricted to the case of N=1 supersymmetry, i. e. there is only one supersymmetric generator and thus only one supersymmetric partner for every particle. A supersymmetric transformation transfers every bosonic state into a fermionic state and vice versa

$$Q | \mathrm{boson} \rangle = | \mathrm{fermion} \rangle$$

 $Q | \mathrm{fermion} \rangle = | \mathrm{boson} \rangle.$ (1.2.1)

The most important (anti-) commutation relations for SUSY algebra with spinors Q are

$$\begin{aligned} \{Q_{\alpha}, Q_{\beta}\} &= \{Q_{\dot{\alpha}}^{\dagger}, Q_{\dot{\beta}}^{\dagger}\} = 0, \\ [Q_{\alpha}, P_{\mu}] &= [Q_{\dot{\alpha}}^{\dagger}, P_{\mu}] = 0, \\ \{Q_{\alpha}, Q_{\dot{\alpha}}^{\dagger}\} &= 2\sigma_{\alpha\dot{\alpha}}^{\mu} P_{\mu}. \end{aligned}$$

$$(1.2.2)$$

 P_{μ} denotes hereby the four component generator of translations. Additionally, it is $\sigma^{\mu} = (1, \sigma_i)$ with the Pauli matrices σ_i . From the second relation in (1.2.2) it follows

$$[Q_{\alpha}, P^2] = [Q_{\dot{\alpha}}^{\dagger}, P^2] = 0.$$
 (1.2.3)

Equation 1.2.3 implies, that particles that are transformed into each other with the generator Q need to have same eigenvalues of P^2 , thus, also same masses. This impose obviously a problem, since no "scalar electron" was ever found with a mass of 0.51 MeV. This problem will be discussed later.

227

240

241

244

245

246

247

248

249

250

In Supersymmetry, all particles and their partner particles are described by so-called supermultiplets. Since the generators of the gauge group commute with the generators of supersymmetry, all particles within one supermultiplet have same quantum numbers, besides the spin (as shown in Eq. 1.2.3 they have also same masses). In a renormalisable theory, there are two different types of supermultiplets: chiral multiplets, which contain a two-component Weyl spinor and a complex scalar field and vector multiplets with a vector boson and a two-component Weyl spinor. The number of degrees of freedom are thus for chiral multiplets for on-shell particles

 $n_f = 2$, due to the two-component Weyl spinor $n_b = 2$, due to the complex scalar field,

28 and for vector multiplets for on-shell particles

 $n_f = 2$, due to the two-component Weyl spinor $n_b = 2$, due to the vector field.

As mentioned before, in a realistic extension of the Standard Model, Supersymmetry 229 cannot be exact, since no supersymmetric particles have been found which have the same 230 masses as their SM partners. This implies, that SUSY must be broken. There are many 231 ideas how the breaking can actually happen. However, since up to now, only little is known 232 about the breaking mechanism, usually further terms which break SUSY explicitly, are 233 added by hand to the Lagrangian density. These terms can parametrise SUSY breaking 234 without the knowledge about the breaking mechanism. One condition is however imposed 235 on the supersymmetry breaking terms: they should not spoil the naturalness of the new 236 theory, i.e. no new quadratic divergencies shall occur due to these terms. Therefore, 237 they are called soft-breaking terms. How they actually look, will be explained in the 238 Section 1.2.1. 239

Finally, it shall be discussed how Supersymmetry can give possible answers to the short-comings of the Standard Model, discussed in Section 1.1.4.

Radiative corrections by fermions always have a factor -1 compared to bosonic corrections. Thus, calculating radiative corrections of the Higgs boson mass in a supersymmetric theory leads in addition to the corrections by SM particles also to further corrections by SUSY particles. If SUSY were exact, the quadratic divergencies Δm_H^2 would exactly cancel. However, as argued, SUSY must be broken. The cancellation of quadratic divergencies can therefore only be assured, if the breaking is not too drastic and only logarithmic divergencies remain. To avoid a new source of fine-tuning, the soft-breaking parameters should be of the order $M_{\rm soft} \sim 100 \, {\rm GeV} - 1000 \, {\rm GeV}$.

Even though, it is not possible to implement gravity within a supersymmetric extension

255

256

257

258

260

261

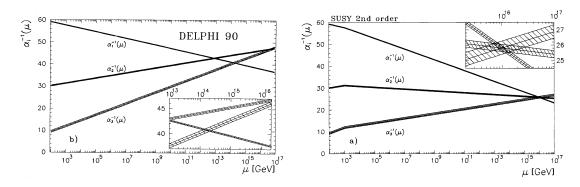

Figure 1.2.1: The running of the gauge couplings in the Standard Model (left) and in the minimal supersymmetric extension of the SM (right). Taken from [28].

of the Standard Model, theories that are able to include gravity (string theories) require also Supersymmetry. 252

The renormalisation group equations change under a supersymmetric extension of the 253 Standard Model. By this, a unification of the gauge couplings at a GUT scale of about 10¹⁶ GeV is possible, as can be seen in Fig. 1.2.1. It can be nicely seen, that all three gauge couplings cross each other within the uncertainties.

Besides these arguments, SUSY can also give an answer to the problem of non-visible matter in the universe. If the conservation of the so-called R-parity is required, the lightest supersymmetric particle (LSP) is stable. If this particle is only weakly interacting, it can serve as a good candidate to explain fully or partially the sources of the relic density. R-parity is a multiplicative quantum number with

$$P_R = 1$$
 SM particles $P_R = -1$ SUSY particles.

If R-parity is conserved, only terms are allowed in the Lagrangian density, that contain an 262 even number of supersymmetric particles. Therefore, no single SUSY particle can decay 263 into only SM particles and thus, the LSP is stable.

1.2.1 The MSSM

The supersymmetric extension of the Standard Model with a minimal particle content is called the Minimal Supersymmetric Standard Model (MSSM). In the following section, the particle content of the MSSM is introduced.

9 1.2.1.1 The particle content of the MSSM

In N=1 Supersymmetry, every SM particle has exactly one supersymmetric partner particle, which leads to a doubling of the particle content in the MSSM with respect to the SM. Additionally, there is a necessity for a second Higgs doublet. The second doublet is needed to ensure the holomorphicity of the superpotential when also mass terms for the up-type particles shall be created. Furthermore, the MSSM stays only free from anomalies if there is a further Higgs doublet. This leads to the fact, that in the MSSM, there are five Higgs bosons instead of only one as in the SM. The complete particle content of the MSSM is depicted in Tables 1.2.1 and 1.2.2.

Since in supersymmetric theories only left-handed Weyl spinors appear in the Lagrangian density, the right-handed are described as charge conjugated spinors of the left-handed spinors.

Table 1.2.2: Vector supermultiplets in the MSSM

285 The superpotential

The superpotential of the MSSM contains the self interaction terms of the Higgs bosons and generates the interaction terms of the Higgs bosons with the fermions and their superpartners. As already noted, it is very common to assume R-parity conservation. Hence, no
terms appear in the Lagrangian that would violate lepton or baryon number conservation
and the lightest supersymmetric particle is stable. Thus, all possible terms are

$$W_{\text{MSSM}} = \mu H_u \cdot H_d - Y_u^{ij} H_u \cdot Q_L^i u_R^{cj} + Y_d^{ij} H_d \cdot Q_L^i d_R^{cj} + Y_e^{ij} H_d \cdot L_L^i e_R^{cj},$$
(1.2.4)

with the dot product defined as in [26]

$$A \cdot B = \epsilon^{\alpha\beta} A_{\alpha} B_{\beta} = A_1 B_2 - A_2 B_1. \tag{1.2.5}$$

292 The soft-breaking Lagrangian density

Since Supersymmetry is broken, explicit SUSY breaking terms are added to the Lagrangian density. In order not to introduce new sources of quadratic divergencies, only bilinear and trilinear terms appear in the soft-breaking Lagrangian

$$-\mathcal{L}_{soft}^{MSSM} = m_{H_{u}}^{2} H_{u}^{\dagger} \cdot H_{u} + m_{H_{d}}^{2} H_{d}^{\dagger} \cdot H_{d} + (B\mu H_{u} \cdot H_{d} + h.c.)$$

$$+ m_{\tilde{Q}ij}^{2} \tilde{Q}_{Li}^{\dagger} \cdot \tilde{Q}_{Lj} + m_{\tilde{u}ij}^{2} \tilde{u}_{Ri}^{c\dagger} \cdot \tilde{u}_{Rj}^{c} + m_{\tilde{d}ij}^{2} \tilde{d}_{Ri}^{c\dagger} \cdot \tilde{d}_{Rj}^{c}$$

$$+ m_{\tilde{L}ij}^{2} \tilde{L}_{Li}^{\dagger} \cdot \tilde{L}_{Lj} + m_{\tilde{e}ij}^{2} \tilde{e}_{Ri}^{c\dagger} \cdot \tilde{e}_{Rj}^{c}$$

$$+ \left(- (A_{u}Y_{u})_{ij} H_{u} \cdot \tilde{Q}_{Li} \tilde{u}_{Rj}^{c} + (A_{d}Y_{d})_{ij} H_{d} \cdot \tilde{Q}_{Li} \tilde{d}_{Rj}^{c} \right)$$

$$+ (A_{e}Y_{e})_{ij} H_{d} \cdot \tilde{L}_{Li} \tilde{e}_{Rj}^{c} + h.c.$$

$$+ \left(M_{1} \tilde{B} \tilde{B} + M_{2} \tilde{W}_{a} \tilde{W}_{a} + M_{3} \tilde{g}_{i} \tilde{g}_{i} + h.c. \right)$$

$$(1.2.6)$$

The first line contains mass terms for the Higgs bosons, the second and third line for the 296 sfermions. In the fourth and fifth line the trilinear couplings between the Higgs bosons 297 and the sfermions appear. Finally, the last line give rise to mass terms for the gauginos. 298 Because of the soft-breaking terms, the MSSM contains more than 100 free parameters. Constraining the MSSM is thus a difficult task and usually in experimental particle physics, constrained versions of the MSSM or assumptions at the GUT scale are used to report the 301 impact of searches on SUSY. In the following a short introduction of the phenomenological 302 MSSM is given. With its reduced parameter space, it allows to elaborate on long-lived 303 particles in the MSSM in a much easier way. 304

305 1.2.1.3 The phenomenological MSSM

The phenomenological MSSM (pMSSM) imposes constraints that are reasonable in the sense to fulfil current observations and still keep the phenomenological richness of the MSSM [29]. The following assumptions are imposed (in [29] more detailed information about these assumptions can be found):

No new sources of CP violation,

310

311

321

- No flavour changing neutral currents,
- First and second generation universality.
- These assumption reduce the number of SUSY parameters to only 19. The remaining free parameters are the following:
- $\tan \beta$ (the ratio of the vacuum expectation values of the two Higgs doublets)
- M_A (the mass of the pseudo-scalar Higgs boson)
- μ (the Higgs mass parameter)
- M_1, M_2, M_3 (bino, wino and gluino mass parameters, respectively)
- $m_{\tilde{q}}, m_{\tilde{l}}, m_{\tilde{u}}, m_{\tilde{d}}$ and $m_{\tilde{e}}$ (the first and second generation mass parameters)
- $m_{\tilde{O}}, m_{\tilde{L}}, m_{\tilde{t}}, m_{\tilde{b}}$ and $m_{\tilde{\tau}}$ (the third generation mass parameters)
 - A_t , A_b and A_τ (third generation trilinear couplings).

1.2.2 Supersymmetry breaking

As already noted, the mechanism of supersymmetry breaking is unknown. There exists however, several ideas how to spontaneously break supersymmetry. All mechanism have in common that they need to happen at high energies in a hidden sector. "Messenger" particles are introduced which mediate the breaking to the TeV scale. This, however, implies that supersymmetry breaking is a question of high-energy physics and one can always parametrise the breaking by the soft breaking terms introduced in Section 1.2.1.2.

The most popular breaking mediation mechanisms is gravity-mediated Supersymmetry breaking [30] and gauge-mediated supersymmetry breaking [31].

1.3 Long-lived particles in the MSSM

There are various mechanisms how particles can be long-lived, such as small couplings or supressed decays because of high mediator masses (weak interaction). For a comprehensive review, the reader is referred to [32].

In this thesis, the focus is set on particles that have a long lifetime due to a small decay phase space. A phase space suppression is possible when the mass splitting between the decay particle and one of the decay products is very small. In Part 2, a search for highly ionising, short tracks is presented. This search is motivated by long-lived charginos, that are nearly mass-degenerate with the lightest supersymmetric particle, the neutralino.

The underlying mechanism of this mass-degeneracy will be addressed in the next paragraphs.

In the MSSM, the lightest chargino $(\tilde{\chi}_1^{\pm})$ and the lightest neutralino $(\tilde{\chi}_1^0)$ can be almost mass-degenerate, when the wino mass parameter (M_2) is smaller than the bino (M_1) and higgsino (μ) mass parameters. This can be seen in the masses of the interaction eigenstates. The following expressions are approximate neutralino and chargino mass terms for $M_2\mu > m_W^2 \sin 2\beta$ and $|M_2 \pm \mu|, |M_1 \pm \mu| \gg m_Z$ (taken from [33])

$$m_{\tilde{B}} \simeq M_{1} + \frac{m_{Z}^{2} (M_{1} + \mu \sin 2\beta) \sin^{2} \theta_{W}}{M_{1}^{2} - \mu^{2}}$$

$$m_{\tilde{W}} \simeq M_{2} + \frac{m_{Z}^{2} (M_{2} + \mu \sin 2\beta) \cos^{2} \theta_{W}}{M_{2}^{2} - \mu^{2}}$$

$$m_{\tilde{H}_{1}^{0}} \simeq |\mu| + \frac{m_{Z}^{2} (1 - \sin 2\beta) (\mu + M_{2} \sin^{2} \theta_{W} + M_{1} \cos^{2} \theta_{W}) sqn(\mu)}{2 (\mu + M_{2}) (\mu + M_{1})}$$

$$m_{\tilde{H}_{2}^{0}} \simeq |\mu| + \frac{m_{Z}^{2} (1 + \sin 2\beta) (\mu - M_{2} \sin^{2} \theta_{W} - M_{1} \cos^{2} \theta_{W}) sqn(\mu)}{2 (\mu - M_{2}) (\mu - M_{1})}$$

$$(1.3.1)$$

347

$$m_{\tilde{W}^{\pm}} \simeq M_2 + m_W^2 \left[\frac{M_2 + \mu \sin 2\beta}{M_2^2 - \mu^2} \right]$$

$$m_{\tilde{H}^{\pm}} \simeq |\mu| + m_W^2 sgn(\mu) \left[\frac{\mu + M_2 \sin 2\beta}{\mu^2 - M_2^2} \right]$$
(1.3.2)

It is obvious from Eqs. 1.3.1 and 1.3.2, that if $M_2 < M_1$, $|\mu|$, the lightest neutralino state is wino-like and is fully mass-degenerate on tree level with the lightest chargino. Thus, the mass differences between $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_1^0$ is only determined by higher loop contributions, making the mass splitting naturally very small. Furthermore, recent analyses of the pMSSM parameter space [34, 35] show, that almost pure wino-like neutralinos often come along with wino-like charginos and their mass splitting is typically of the order of $\sim 160 \,\mathrm{MeV}$ [34].

55 1.3.1 Previous searches and constraints from indirect searches

Several previous searches are sensitive on SUSY scenarios with almost mass-degenerate wino-like charginos and neutralinos. In the following an overview about these previous searches will be given. Additionally, constraints from indirect searches are summarised.

359 Searches at LEP

Several searches at LEP were hunting for almost mass-degenerate neutralino-chargino scenarios [36–39]. These searches were looking for events with a high-energetic initial state radiated photon leading to missing energy in events with chargino-pair production and invisible decay products. The excluded parameter regions by these searches can be found in [40] and are depicted in Fig. 1.3.1. The searches were interpreted for M_1 and M_2 almost degenerate and with a large unified scalar mass m_0 leading to sneutrino masses larger than 500 GeV. Charginos are excluded up to a mass of 92.4 GeV [40].

Searches at ATLAS at 7 and 8 TeV

At the ATLAS experiment at the LHC, searches for events with a dissapearing track signature were conducted at $\sqrt{s}=7\,\mathrm{TeV}$ [41] as well as at $\sqrt{s}=8\,\mathrm{TeV}$ [42]. Furthermore, a search for metastable particles with high ionisation loss was performed with $\sqrt{s}=8\,\mathrm{TeV}$ data [43]. These searches were interpreted within an anomaly-mediated Supersymmetry breaking model [44] with $\tan\beta=5$ and $\mu<0$. The excluded parameter space by these searches is shown in Fig. 1.3.2. Models with charginos down to lifetimes of 0.06 ns can be excluded.

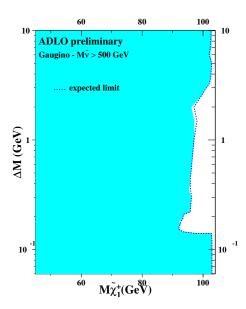

Figure 1.3.1: Observed and expected exclusion limits in the $m_{\tilde{\chi}_1^{\pm}} - \Delta m \left(\tilde{\chi}_1^{\pm}, \tilde{\chi}_1^0 \right)$ plane for almost degenerate M_1 and M_2 and a large nified scalar mass m_0 . Taken from [40].

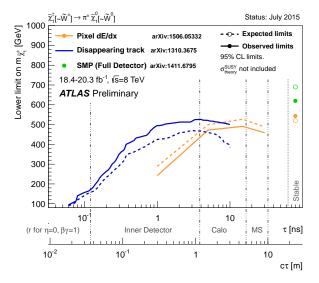

Figure 1.3.2: Excluded parameter space in the $m_{\tilde{\chi}_1^\pm} - \tau_{\tilde{\chi}_1^\pm}$ plane for an AMSB model with $\tan\beta = 5$ and $\mu > 0$. Only chargino pair production is taken into account. The area below the curves is excluded. Taken from [45].

Searches at CMS at 7 and 8 TeV

There are several searches at the CMS experiment at the LHC that are sensitive to long-lived wino-like charginos. Among them is the search for long-lived charged particles [46], which searched for heavy particles with large energy deposits in the tracker. Furthermore, there is the search for disappearing tracks [47] which analysed events with disappearing tracks in the tracker with respect to wino-like charginos almost mass-degenerate with the lightest neutralino. Since the latter search is more sensitive to shorter lifetime, only the exclusion limits derived by this search are shown in Fig. 1.3.3. The disappearing track search by CMS shows are very similar sensitivity as the searches done at the ATLAS experiment.

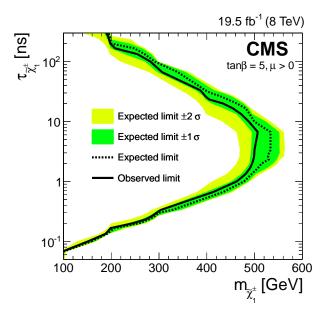

Figure 1.3.3: Excluded parameter space in the $\tau_{\tilde{\chi}_1^{\pm}} - m_{\tilde{\chi}_1^{\pm}}$ plane for wino-like charginos. The region left to the curve is excluded. Taken from [47].

Indirect searches

Finally, also results from indirect dark matter searches constrain the SUSY parameter region of wino-like charginos and neutralinos.

You found some good papers!!!!
